## Abstract

For many patients with severe Covid-19 disease of the pre-Omicron era, recovery is far from over with the end of acute symptoms. The authors of this paper have reviewed the currently available studies and conclude that Long-Covid appears to be a serious, sometimes even life-threatening syndrome. However, it seems to have good prospects for full recovery with multidisciplinary and evidence-based post-treatment care, which is, however, still lacking in Europe and North America. The Omicron variant appears to be a game changer in this regard as well. So far it seems that Long Covid is no common consequence of Sars-2-Omicron Disease.
