Abstract

The role of ISG15 (Interferon-Stimulated Gene 15) is becoming increasingly acknowledged in cancer, pathogen infection and inflammatory immune diseases. ISG15 expression increases in human psoriatic skin, and genetic mutations of ISG15 cause dermatological alterations. Here, we show that ISG15 deficiency leads to reduced inflammation and swelling in a murine model of allergic contact dermatitis (ACD). Bone marrow transplantation and adoptive transfer approaches demonstrate that ISG15 alters dendritic cell (DC) responses in the ACD mouse model. Consistently, *Isg15*-deficient DCs secrete reduced amounts of pro-inflammatory cytokines, including IL-1 β and IL-12. This study opens new avenues to potentiate immunotherapies to treat immune-related dermatological disorders.
